

How bamboo fabric is made

The diagram depicts the process by which bamboo is processed into *textile products*. Overall, it is clear that the production involves three principal stages, beginning with the cultivation and harvesting of bamboo, followed by mechanical and chemical treatments to produce fiber, and culminating in the manufacture of finished *garments*.

Notably, the process combines both natural and industrial procedures.

In the initial natural stage, bamboo plants are cultivated during the spring and are subsequently harvested by hand in the autumn. Once collected, the bamboo stalks are cut into narrow strips using a circular saw. These strips are then mechanically crushed to produce a liquid pulp.

Following this, the pulp undergoes chemical processing. It is first passed through a filter to separate the longer fibers from the remaining liquid. Water and amine oxide are then added in order to soften the fibers, making them suitable for spinning. The softened material is spun into threads, which are subsequently woven into sheets of fabric. In the final stage, this fabric is used to manufacture clothing products ready for retail sale.

The process diagram shows the mass manufacturing of coconut oil.

The diagram depicts the process by which coconut-based products are produced. Overall, it is evident that the process consists of a series of linear steps, beginning with harvesting and preparation, followed by extraction and purification, and concluding with packaging and distribution.

Initially, coconuts are harvested from palm trees, with the timing of this stage playing a crucial role in determining product quality. The harvested coconuts **then** undergo de-husking, **after which** the inner flesh is grated using a mechanical grater. The grated material is **subsequently** weighed to ensure consistency before being laid out and dried under sunlight.

Once dried, the coconut material is pressed using a hydraulic press in order to extract the liquid. This extracted substance **then** enters a clarifying stage, **during which** impurities are removed. The clarified liquid is filtered further to achieve a purer final product. In the final stages of the process, the refined coconut product is packaged into various containers and subsequently prepared for shipping, marking the completion of the production cycle.
